New knowledge on how antibiotic resistance genes (ARGs) are formed and spread is required for a better understanding of the global problem. To provide such data, the metagenomic diversity of ARGs was studied in a survey of uncultivated microbial life from a site with elevated levels of ARGs. Analysis of DNA extracted from water from the same sampling point showed diverse ARGs and, because only 70% of bacteria were cultivable, that ARG diversity was a result of the activity of uncultivable bacteria, as most ARGs were absent from the cultivable bacteria. The presence of ARGs in uncultivated bacteria was confirmed by community analysis of DNA from the water sample using a flow cytometric method, which showed that the majority of the DNA in the water sample was of bacterium-like size. The presence of ARGs in uncultivated microbes was confirmed by PCR analysis, and three ARGs, tetW, sulI and sulII, showed the same phylogenetic pattern as their associated transposons Tn5282, Tn5292 and Tn
