A: You can use a regular expression to match patterns like: string path = @"E:\Poetica.zip"; string pattern = @"(?

I want to make a PHP function that would remove ALL repeated values in an array: \$arr = array ("banana", "apple", "orange", "banana", "orange"); I want to get array("banana", "apple", "orange") How is it possible? A: You can use array_unique() like this: \$arr = array ("banana", "apple", "orange", "banana", "orange"); \$unique = array_unique(\$arr); print_r(\$unique); Output Array ([0] => banana [1] => apple [2] => orange) Activity-based imaging of nonenzymatic cyclization of adenine. Here we show that adenine is cyclized via a nucleophilic attack on its exocyclic amino group in alkaline solution, affording an intramolecular cyclic 1,N(6)-H-adenosine derivative (Ketal-Ado), as confirmed by (1)H NMR spectroscopy, electrospray ionization mass spectrometry (ESI-MS), and cyclic voltammetry. For the same reaction, the adenine analogues, 2,6-diaminopurine and 6-N-methylanthranilate, cyclize in acidic solution to form the respective intramolecular cyclic 1,N(6)-H-adenine derivatives. Ketal-Ado exhibits lower solubility than adenosine and has limited water solubility; however, the fluorescence emission of the cyclic compound decreases upon dissolution in water.Q: Why is the computation of circular product of the linear operator SAS with itself equal to SA^TAS? I am reading a book "Convex Analysis" by K. R. Parthasarathy, which is the best introduction to convex analysis that I have come across. The author defines a linear operator SAS on a vector space X as follows: If SAS is an operator on X, then a linear operator SAS on X is a map SA:X to X such that for any x, 2d92ce491b
