The recent emergence of multimedia services on the Internet has increased demand for data delivery services. In the fourth generation (4G) cellular network (long term evolution, LTE), is now a key enabling technology. Such 4G cellular networks comprise a large number of evolved base stations, termed evolved Node-Bs (eNBs), which are connected to core networks in turn connected to a number of user equipment devices, which are also termed user equipment-UEs. As used herein, the term “user equipment”, “UE”, “user equipment device” or “UE device” is used to refer to any device that can be used for communication, such as a mobile phone, smart phone, personal digital assistant (PDA), tablet computer, laptop computer, or other suitable device.

In the 3G mobile network systems, many users access services on their mobile phones (both at home and outside of home) which provide voice, SMS, and data services. This is supported in the networks by a mobile communications network comprising a large number of cell sites in communication with the user equipment devices. Each of these cell sites, or base station, comprises radio equipment which provides a radio link between the base station and the user equipment device. The radio link is provided over a frequency channel (which comprises a frequency range of frequencies). This frequency channel is a part of a frequency range that is divided into a plurality of frequency channels. These frequency channels are contiguous or non-contiguous. A frequency range is a frequency band. Frequency ranges are divided into channels. Channel is a frequency range allocated to one communication service. A typical example of a frequency range is a radio frequency (RF) range. Communication between user equipment devices and the radio equipment in the base station are provided by
